Ok, despite it being a hospital, dust is everywhere. Dust can be found no matter how sterile an environment is. These definitely could be dust or moisture. However, three things stand out to me. First is how different the small dust particle is on the far left compared to the other anomalies. Second is how those anomalies all look very similar. The last thing is that the one on the far right is cut on a straight edge. I don't know what it all means, but those things stand out to me.

Let me ask you this, was it raining when you came into the hospital? This could also be caused by tiny water particles. These actually look more like refractive effects rather than the reflective effects of most dust particles.

The difference is normally seen in the shape. Reflective effects usually create some "mostly round" type of particles. Where as refractive effects create odd shaped particles because of the curvature of the curvature of the object.
